Abstract

A quantum field theoretical model for the dynamics of the disoriented chiral condensate is presented. A unified approach to relate the quantum field theory directly to the formation, decay and signals of the DCC and its evolution is taken. We use a background field analysis of the $O(4)$ sigma model keeping one-loop quantum corrections (quadratic order in the fluctuations). An evolution of the quantum fluctuations in an external, expanding metric which simulates the expansion of the plasma, is carried out. We examine, in detail, the amplification of the low momentum pion modes with two competing effects, the expansion rate of the plasma and the transition rate of the vacuum configuration from a metastable state into a stable state. We show the effect of DCC formation on the multiplicity distributions and the Bose-Einstein correlations.

1 Introduction

The mechanism of spontaneous symmetry breaking [1] occupies an important role in particle physics, cosmology [2] and condensed matter physics [3]. The understanding of this phenomenon has lead to cross fertilization between these fields and many new ideas have emerged [4]. When a symmetry is spontaneously broken by a vacuum state, it is well known that thermal effects at equilibrium can restore the broken symmetry [5]. Typically, there exists a critical temperature T_c at which the effective potential as a function of some order

*This paper is dedicated to Prof. Yoichiro Nambu for his 82nd birthday.

parameter ϕ develops an absolute minimum at $\phi = 0$ and the system undergoes a phase transition and relaxes to this minimum at higher temperature. A manifestation of this, in a second order phase transition is that at $T = T_c$ the order parameter fluctuates at all scales and long wavelength oscillations occur [6],[7]. For non-equilibrium situations, the dynamics of the transition of a system from a symmetric to a broken symmetry state leads to the formation of new structures and the generation of entropy in the form of particle production[8, 9, 3]. In high energy physics, there are two well known examples of symmetry breaking: electroweak symmetry-breaking and chiral symmetry-breaking in strong interactions. One of the main features of QCD, the underlying theory of strong interactions, is the spontaneous breaking of its approximate $SU(2)_L \times SU(2)_R$ chiral symmetry. Spontaneous breaking of this approximate symmetry explains the very small pion masses. If the symmetry breaking were exact, pions would be massless Nambu-Goldstone bosons. Another consequence of this symmetry breaking is the presence of a non-vanishing quark condensate in the vacuum. It is believed that at very high temperature a quark-gluon plasma is formed in which chiral symmetry is restored, and much effort is being made to explore such a phase transition by means of high-energy hadron or heavy-ion collisions [10]. The question is : How do we test the spontaneous symmetry breaking mechanism in a non-equilibrium process directly? Can we create a suitable condition so that the vacuum state is disturbed for a small region of space-time and observe different excitations and domain structures in the vacuum?

Recently it has been conjectured that this maybe possible for the chiral symmetry-breaking in strong interactions given the present high energy physics facilities [11, 13, 15, 16].

To describe aspects of QCD related to this symmetry, it is convenient to introduce an effective theory, to use a low energy effective sigma model as a model for the QCD phase transition because it respects the $SU(2) \times SU(2)$ chiral symmetry of QCD with two light flavours of quark and it contains a scalar field (Σ) that has the same chiral properties as the quark condensate. The Σ field can thus be used to represent the order parameter for the chiral phase transition. The chiral four-vector of fields $(\Sigma, \boldsymbol{\pi})$, where Σ represents the quark condensate and the three π_i are the pion fields. In the physical vacuum, $(\Sigma, \boldsymbol{\pi})$ points in the Σ direction. If the chiral symmetry were exact then there would be a “chiral circle” of states degenerate with this vacuum state. In practice, the symmetry is explicitly broken by the current quark masses and so there is a unique vacuum.

Because of this circle of nearly degenerate field configurations, as the chirally restored plasma cools and returns to the normal phase, the system could form regions in which the chiral fields are misaligned, that is, chirally rotated from their usual orientation along the Σ direction. There has been much recent interest in this phenomenon, which is known as a disoriented chiral condensate (DCC). If such a state were formed, it would lead to anomalously large event-by-event fluctuations in the ratio of charged to neutral pions.

A region of DCC can be thought of as *a cluster of pions of near identical momentum*

around zero(coherently produced) with an anomalously large amount of fluctuation of the neutral fraction. In order to produce such a state in a quark gluon plasma, the hot plasma must evolve far from equilibrium and in particular it must reach an unstable configuration such that the long-wavelength pion modes are amplified exponentially when the system relaxes to the stable vacuum state. Thus questions of whether a DCC forms and how it evolves cannot be addressed in the framework of equilibrium thermodynamics. Techniques for applying QCD directly to such situations do not exist at present. To explain these non-equilibrium phenomena, we need to restructure the theory of phase transitions to incorporate the micro structures (or states) instead of macro structures. For this we need to set up a theory at the quantum level. Some attempts have been made [17],[19],[20],[21],[22], but to our knowledge these are incomplete as they do not incorporate the disorientation of the condensate and the evolution of the plasma in one unified picture. In his talk at Trento, [23] Bjorken pointed out some of the unresolved issues concerning the DCC called the *DCC trouble list*. They were:

- (a) Are coherent states the right quantum DCC description, or should one go beyond to squeezed states, etc.
- (b) How does one link DCC thinking to quantum effects in the data, especially the BoseEinstein correlations. Is DCC just another way of talking about the same thing?
- (c) How does one enforce quantum number conservation, especially charge? [24]
- (d) DCC production may imply anomalous bremsstrahlung, due to the large quantum fluctuations in charge. Can this be calculated from first principles?
- (e) Can one really set up the problem at the quantum field theory level?

In this paper we lay the foundation for a unified quantum picture of the DCC with and without orientation and give our answers to these questions.

2 The Model

In most treatments of DCC formation, the classic Gellman-Levy lagrangian [29] is used. For a more general treatment which encompasses this Lagrangian, we use the field theoretic $O(4)$ symmetric sigma model with Lagrangian density

$$L = \left(\frac{1}{2} \dot{\Phi}_i^2 - \frac{1}{2a^2} (\nabla \Phi_i)^2 - \frac{1}{2} m^2 \Phi_i^2 - \frac{\lambda}{4} (\Phi_i^2)^2 \right) \quad (1)$$

$$\Phi_i = \begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \Phi_3 \\ \Phi_4 \end{pmatrix} \quad (2)$$

where Φ_i , $i = 1..4$ are real scalar fields.

We note here that the potential we use is not the one traditionally used by the early practitioners of DCC analyses. Thus, for later comparison with the dynamical equations for the pions used as starting points for analysing the DCC, we will later relate the potential that we have chosen to the traditional potential in the Gell-Mann, Levy model [33]. The Lagrangian density in the Gell-Mann, Levy model is given by

$$L = \frac{1}{2} (\partial_\mu \vec{\pi} \partial^\mu \vec{\pi} + \partial_\mu \Sigma \partial^\mu \Sigma) - \frac{\lambda}{4} (\vec{\pi}^2 + \Sigma^2 - v^2)^2 + H\Sigma. \quad (3)$$

The action is

$$S = \int d^4x \left[\frac{1}{2} (\partial_\mu \phi^a \partial_\mu \phi_a - \frac{\lambda}{4} (\phi^a \phi_a - v^2)^2 + H\Sigma \right]. \quad (4)$$

The basic object of study is then the chiral field

$$\vec{\phi}(r, t) = \Sigma(r, t) + i\tau \cdot \vec{\pi}(\mathbf{r}, \mathbf{t}), \quad (5)$$

where $\Sigma(r, t)$ and $\vec{\pi}(r, t)$ are the scalar and vector fields respectively of the $O(4)$ vector $\vec{\phi} = (\Sigma, \vec{\pi})$ and τ are the Pauli matrices.

To make contact with the physical constants λ , v and H are related to the physical quantities, $f_\pi = 92MeV$ (pion form factor) and $m_\pi = 138MeV/c^2$ by the relations

$$\begin{aligned} m_\pi^2 = \frac{H}{f_\pi} &= \lambda(f_\pi^2 - v^2) \\ m_\Sigma^2 &= 3\lambda f_\pi^2 - \lambda v^2 \approx 2\lambda f_\pi^2 = 600MeV/c^2 \\ \lambda &= \frac{m_\Sigma^2 c^2 - m_\pi^2 c^2}{2f_\pi^2} = 20.14, \\ <v> &= \left[\frac{m_\Sigma^2 - 3m_\pi^2}{m_\Sigma^2 - m_\pi^2} f_\pi^2 \right]^{\frac{1}{2}} = 86.71MeV \\ H &= m_\pi^2 c^2 f_\pi = (120.55MeV)^3. \end{aligned} \quad (6)$$

Note that the fermionic part is neglected here, since the focus is on the condensate formed in the symmetry broken phase where quark degrees of freedom are already confined. With the transformation, $\Sigma \rightarrow \Sigma - v$, the minimum of potential is at $<\phi^2> = <\Sigma^2 + \pi^2> = <v>^2 = f_\pi^2$ and the usual equilibrium vacuum state is an ordered state $<\Sigma> = <v> = f_\pi$ and $<\pi> = 0$.

Now consider the dynamic evolution of the system in a hot quark gluon plasma. When the temperature $T \geq T_c$ the system reaches a state of restored symmetry $<\phi^2> = 0$. If the subsequent expansion of the plasma is adiabatic, the $<\phi>$ field gradually relaxes to

the equilibrium state as the system cools to below T_c . This is called the "annealing" or adiabatic scenario. It was first pointed out in reference [13] that if the cooling process is very rapid and the system is out of equilibrium, i.e., in the event of a sudden quench from a state of restored symmetry to a state of broken symmetry such as that occurring in a rapidly cooling expanding plasma, the configuration of the ϕ field will lag behind the expansion of the plasma and there is a mismatch of the configurations and their evolution. After a quench, the high temperature configuration does not have time to react to the sudden change of the environment, thus the vacuum expectation value $\langle \phi \rangle$ would stay what it was at high temperature for a while and then relax to its equilibrium value. This results in the formation of DCC domains and is known as the *Baked Alaska* [14] scenario.

Another non-equilibrium situation that can arise is one where the system can go through a meta-stable disordered vacuum $\langle \Sigma \rangle = f_\pi \cos(\theta)$ $\langle \pi \rangle = f_\pi \bar{n} \sin(\theta)$ and then relax by quantum fluctuations to an equilibrium configuration. Here θ measures the degree of disorientation of the condensate in isospin space.

In both these non-equilibrium situations, the canonical approach to the full quantum evolution of the fields is extremely difficult to carry out explicitly. However, we may study the quantum evolution of the mean field and include fluctuations. In calculating the effective Hamiltonian we use the $O(4)$ symmetric linear sigma model, whose Lagrangian density is given by (1). It is easy to see that with the identification $\Phi^2 = (\Sigma^2 + \pi^2 - f_\pi^2)$, and, $\Sigma \rightarrow \Sigma - v$, the effective potential in the $O(4)$ linear sigma model is the same as the Gell-Mann Levy model. We will use this identification when considering the evolution of the pion field.

The choice of metric is dictated by the simple spherical geometry of the problem. Assuming a homogeneous expansion of the plasma, a Robertson-Walker type of metric is chosen with an expansion rate $a(t)$. This will allow us to examine the competing rates leading to "rolling down rate" of the vacuum and the expansion rate $a(t)$. The line element describing the expansion of the plasma bubble is chosen to be:

$$ds^2 = dt^2 - a(t)^2 d\vec{x}^2, \quad (8)$$

where $a(t)$ is the expansion parameter.

The action of the $O(4)$ sigma model in this metric becomes:

$$S = \int d^3x dt a(t)^3 \left(\frac{1}{2} \dot{\Phi}_i^2 - \frac{1}{2a^2} (\nabla \Phi_i)^2 - \frac{1}{2} m^2 \Phi_i^2 - \frac{\lambda}{4} (\Phi_i^2)^2 \right), \quad (9)$$

with

$$\Phi_i = \begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \Phi_3 \\ \Phi_4 \end{pmatrix} \quad (10)$$

where Φ_i , $i = 1..4$ are real scalar fields.

We now use a background field analysis to study the quantum effects. Assume Φ_i has a background classical component ϕ_i which satisfies the classical equations of motion:

$$\frac{\delta S}{\delta \Phi_i} \Big|_{\Phi_i=\phi_i} = 0. \quad (11)$$

Treat the quantum field $\hat{\phi}_i$ as fluctuation around classical solution:

$$\Phi_i \longrightarrow \phi_i + \hat{\phi}_i \quad (12)$$

since ϕ_i satisfies the classical equations of motion,

$$S = S[\phi_i] + \frac{1}{2} \hat{\phi}_i \frac{\delta^2 S}{\delta \Phi_i \delta \Phi_j} \Big|_{\Phi=\phi} \hat{\phi}_j + \dots \quad (13)$$

We shall restrict our analysis to quadratic fluctuations only. In addition, we shall also drop the term $S[\phi_i]$ as it is just a constant additive term to the quadratic action. Therefore we shall deal with a quadratic fluctuation action given simply by:

$$S_2 = \frac{1}{2} \hat{\phi}_i \frac{\delta^2 S}{\delta \Phi_i \delta \Phi_j} \Big|_{\Phi=\phi} \hat{\phi}_j. \quad (14)$$

For the particular scalar field action given above, assuming all fields vanish at infinity,

$$\frac{\delta S}{\delta \Phi_j} = -\partial_\mu (a^3 g^{\mu\nu} \partial_\nu \Phi_j) - a^3 m^2 \Phi_j - a^3 \frac{\delta V}{\delta \Phi_j}. \quad (15)$$

Imposing the classical equations of motion, we find that

$$\partial_\mu (a^3 g^{\mu\nu} \partial_\nu \phi_i) + a^3 m^2 \phi_i + a^3 \frac{\partial V}{\partial \phi_i} = 0 \quad (16)$$

where $\frac{\partial V}{\partial \phi_i} \equiv \frac{\partial V}{\partial \Phi_i} \Big|_{\phi_i}$.

The equations of motion in this metric are

$$3 \frac{\dot{a}}{a} \dot{\phi}_i + \dot{\phi}_i^2 - \frac{1}{a^2} \nabla^2 \phi_i + m^2 \phi_i + \frac{\partial V}{\partial \phi_i} = 0. \quad (17)$$

Since we are interested in the dynamics of the fluctuation field, we shall treat the fluctuation field in S_2 as a classical field and S_2 itself as the classical action for its dynamics. While the quadratic part in the fluctuations is reduced to:

$$S_2 = \int d^3 \underline{x} dt \frac{a^3}{2} (\dot{\hat{\phi}}_i^2 - \frac{1}{a^2} (\nabla \hat{\phi}_i)^2 - m^2 \hat{\phi}_i^2 - \hat{\phi}_i \frac{\delta^2 V}{\delta \hat{\Phi}_i \delta \hat{\Phi}_j} \Big|_{\phi} \hat{\phi}_j). \quad (18)$$

We can define a Lagrangian density for studying the dynamics of the fluctuations, $\mathcal{L}$, as follows:

$$\mathcal{L} = \frac{a^3}{2}(\dot{\hat{\phi}}_i^2 - \frac{1}{a^2}(\nabla \hat{\phi}_i)^2 - m^2 \hat{\phi}_i^2 - \hat{\phi}_i \frac{\partial^2 V}{\partial \Phi_i \partial \Phi_j} |_{\phi} \hat{\phi}_j). \quad (19)$$

Carrying out a Legendre transformation, it is easy to write down the Hamiltonian density

$$\mathcal{H} = \frac{1}{2a^3} \hat{p}_i^2 + \frac{a}{2} (\nabla \hat{\phi}_i)^2 + \frac{a^3 m^2}{2} \hat{\phi}_i^2 + \frac{a^3}{2} (\hat{\phi}_i \frac{\partial^2 V}{\partial \Phi_i \partial \Phi_j} |_{\phi} \hat{\phi}_j) \quad (20)$$

where

$$\hat{p}_i = \frac{\delta L}{\delta \dot{\hat{\phi}}_i} = a^3 \dot{\hat{\phi}}_i. \quad (21)$$

We also have

$$\frac{\partial^2 V}{\partial \Phi_i \partial \Phi_j} |_{\phi} = 2\lambda \phi_i \phi_j + \lambda \phi_k^2 \delta_{ij}. \quad (22)$$

Assume that the fluctuation field Φ_i decomposes into its constituents as:

$$\hat{\phi} = \langle \Phi \rangle - \phi = \begin{pmatrix} \pi_1 \\ \pi_2 \\ \pi_0 \\ \Sigma \end{pmatrix}. \quad (23)$$

We have started with an $O(4)$ quartet of scalar fields in order that we can construct the dynamics of quenched pions in the formation of a disoriented chiral condensate. The physical fields are defined so that

$$\pi_+ = \frac{1}{\sqrt{2}}(\pi_1 + i\pi_2); \quad \pi_- = \frac{1}{\sqrt{2}}(\pi_1 - i\pi_2). \quad (24)$$

Analogously, we define the classical background fields as:

$$v_+ = \frac{1}{\sqrt{2}}(v_1 + iv_2); \quad v_- = \frac{1}{\sqrt{2}}(v_1 - iv_2), \quad (25)$$

following the identification:

$$\phi = \begin{pmatrix} v_1 \\ v_2 \\ v_3 = v \\ \sigma \end{pmatrix} \equiv \langle \Phi \rangle. \quad (26)$$

It is easy to see that the action takes the following form:

$$S = \int d^3 \vec{x} dt a^3 \{ \dot{\pi}_+ \dot{\pi}_- - \frac{1}{a^2} (\nabla \pi_+) (\nabla \pi_-) - (m^2 + (4\lambda) v_+ v_- + \lambda v_3^2 + \lambda \sigma^2) \pi_+ \pi_- \}$$

$$\begin{aligned}
& + \frac{1}{2}\dot{\pi}_0^2 - \frac{1}{2a^2}(\nabla\pi_0)^2 - \frac{1}{2}(m^2 + (2\lambda)v_+v_- + 3\lambda v_3^2 + \lambda\sigma^2)\pi_0^2 + \frac{1}{2}\dot{\Sigma}^2 - \frac{1}{2a^2}(\nabla\Sigma)^2 \\
& - \frac{1}{2}(m^2 + (2\lambda)v_+v_- + 3\lambda\sigma^2 + \lambda v_3^2)\Sigma^2 - \lambda(v_-^2\pi_+^2 + v_+^2\pi_-^2 + 2\sigma v_3\pi_0\Sigma \\
& + 2v_-v_3\pi_0\pi_+ + 2v_+v_3\pi_0\pi_- + 2v_-\sigma\pi_+\Sigma + 2v_+\sigma\pi_-\Sigma)\}
\end{aligned} \tag{27}$$

The Hamiltonian for this action can be written as

$$H = H_{neutral} + H_{charged} + H_{mixed}, \tag{28}$$

where

$$\begin{aligned}
H_{neutral} &= \int d^3x dt a^3 \left\{ \frac{(p_{0\pi_0}^2)}{2a^6} + \frac{1}{2a^2}(\nabla\pi_0^2) + \frac{1}{2}(m_\pi^2)(\pi_0)^2 + \frac{(\Omega_\pi^2 - \omega_\pi^2)}{2a^6}\pi_0^2 \right. \\
&+ \left. \frac{(p_{0\Sigma}^2)}{2a^6} + \frac{1}{2a^2}(\nabla\Sigma^2) + \frac{1}{2}(m_\Sigma^2)(\Sigma)^2 + \frac{1}{2a^6}(\Omega_\Sigma^2 - \omega_\Sigma^2)(\Sigma)^2 \right\}
\end{aligned} \tag{29}$$

$$\begin{aligned}
H_{charged} &= \int d^3x dt a^3 \left(\frac{1}{a^6} \{ (p_{0+}p_{0-}) \right. \\
&+ \left. \frac{1}{a^2}(\nabla\pi_-)(\nabla\pi_+) + (m_\pi^2)(\pi_+\pi_-) + \frac{1}{a^6}(\Omega_{\pi_\pm}^2 - \omega_{\pi_\pm}^2)(\pi_+\pi_-) \} \right)
\end{aligned} \tag{30}$$

$$\begin{aligned}
H_{mixed} &= \int d^3x a^3 dt \{ \lambda(v_+^2\pi_-^2 + v_-^2\pi_+^2) \\
&+ (2\lambda)(v_+v_3\pi_-\pi_0 + v_-v_3\pi_+\pi_0 + \sigma v_3\Sigma\pi_0 + v_+\sigma\pi_-\Sigma + \sigma v_-\Sigma\pi_+) \}.
\end{aligned} \tag{31}$$

Where we have also put

$$\begin{aligned}
\frac{\Omega_{\pi_0}^2 - \omega_{\pi_0}^2}{a^6} &= \lambda[v^2 + 2v_3^2] \\
\frac{\Omega_{\pi_\pm}^2 - \omega_{\pi_\pm}^2}{a^6} &= \lambda[v^2 + 2v_+v_-] \\
\frac{\Omega_\Sigma^2 - \omega_\Sigma^2}{a^6} &= \lambda[v^2 + 2\sigma^2]
\end{aligned} \tag{32}$$

and

$$2v_+v_- + v_3^2 + \sigma^2 = v^2. \tag{33}$$

This is the most general Hamiltonian for the pion sigma system in the background field formalism. The background field can now be parametrized through three angles:

$$\phi_i = \begin{pmatrix} v\cos(\rho)\sin(\theta)\sin(\alpha) \\ v\cos(\rho)\sin(\theta)\cos(\alpha) \\ v\sin(\rho)\sin(\theta) \\ v\cos(\theta) \end{pmatrix}. \tag{34}$$

In order to consider all the special cases that are possible in a transparent way, we shall simplify the parametrization of the possible form for the background field to two angles, θ and ρ by letting $\alpha = \frac{\pi}{4}$: then, $v\pm = \frac{v}{\sqrt{2}}\cos(\rho)\sin(\theta)$, $v_3 = v\sin(\rho)\sin(\theta)$, and $\sigma = v\cos(\theta)$.

3 Quantisation

Using standard Canonical quantisation techniques the mode decomposition of the Hamiltonian is:

$$\begin{aligned}
H_{neutral} = & \int \frac{d^3\underline{k}}{(2\pi)^3} \frac{1}{2} \left\{ \frac{\omega_\pi}{a^3} (a_k^\dagger a_k + a_k a_k^\dagger) \right. \\
& + \frac{\omega_\pi}{2a^3} \left(\frac{\Omega_\pi^2}{\omega_\pi^2} - 1 \right) (a_k^\dagger a_k + a_k a_k^\dagger + a_{-k} a_k + a_{-k}^\dagger a_k^\dagger) \\
& \left. + \frac{\omega_\Sigma}{a^3} (d_k^\dagger d_k + d_k d_k^\dagger) + \frac{\omega_\Sigma}{2a^3} \left(\frac{\Omega_\Sigma^2}{\omega_\Sigma^2} - 1 \right) (d_k^\dagger d_k + d_k d_k^\dagger + d_{-k} d_k + d_{-k}^\dagger d_k^\dagger) \right\}
\end{aligned} \tag{35}$$

$$\begin{aligned}
H_{charged} = & \int \frac{d^3\underline{k}}{(2\pi)^3} \left\{ \frac{\omega_\pi}{a^3} (b_k^\dagger b_k + c_k c_k^\dagger) \right. \\
& \left. + \frac{\omega_\pi}{2a^3} \left(\frac{\Omega_{\pi\pm}^2}{\omega_\pi^2} - 1 \right) (b_k^\dagger b_k + c_k c_k^\dagger + b_{-k} c_k + c_{-k}^\dagger b_k^\dagger) \right\}
\end{aligned} \tag{36}$$

$$\begin{aligned}
H_{mixed} = & \int \frac{d^3\underline{k}}{(2\pi)^3} \left\{ \frac{\lambda a^3 v^2 \cos^2(\rho) \sin^2(\theta)}{4\omega_\pi} (b_k b_{-k} + b_k c_k^\dagger \right. \\
& + c_k^\dagger b_k + c_k c_{-k} + c_k^\dagger c_{-k}^\dagger + c_k b_k^\dagger + b_k^\dagger c_k + b_k^\dagger b_{-k}^\dagger) \\
& + \frac{\lambda a^3 v^2 \cos(\rho) \sin(\rho) \sin^2(\theta)}{\sqrt{\omega_\Sigma \omega_\pi}} \\
& \left(b_k a_{-k} + b_k a_k^\dagger + c_k^\dagger a_k + c_k a_{-k} + c_k^\dagger a_{-k}^\dagger + c_k a_k^\dagger + b_k^\dagger a_k + b_k^\dagger a_{-k}^\dagger \right) \\
& + \frac{\lambda a^3 v^2 \sin(\rho) \sin(\theta) \cos(\theta)}{\sqrt{\omega_\pi \omega_\Sigma}} \left(d_k a_{-k} + d_k a_k^\dagger + d_k^\dagger a_k + d_k^\dagger a_{-k}^\dagger \right) \\
& + \frac{\lambda a^3 v^2 \cos(\rho) \sin(\theta) \cos(\theta)}{\sqrt{\omega_\pi \omega_\Sigma}} \\
& \left. \left(b_k d_{-k} + b_k d_k^\dagger + c_k^\dagger d_k + c_k d_{-k} + c_k^\dagger d_{-k}^\dagger + c_k d_k^\dagger + b_k^\dagger d_k + b_k^\dagger d_{-k}^\dagger \right) \right\}
\end{aligned} \tag{37}$$

where

$$\begin{aligned}\frac{\omega_\pi^2(k)}{a^6} &\equiv \frac{\omega_{\pi_0}^2(k)}{a^6} = \frac{\omega_{\pi_\pm}^2(k)}{a^6} = (m_\pi^2 + \frac{k^2}{a^2}) \\ \frac{\omega_\Sigma^2(k)}{a^6} &= (m_\Sigma^2 + \frac{k^2}{a^2})\end{aligned}\quad (38)$$

and

$$\frac{\Omega_\pi^2(k)}{a^6} = \frac{k^2}{a^2} + m_\pi^2 + \lambda(v^2 + 2v_3^2). \quad (39)$$

$$\frac{\Omega_{\pi_\pm}^2(k)}{a^6} = \frac{k^2}{a^2} + m_{\pi_\pm}^2 + \lambda(v^2 + 2v_+v_-). \quad (40)$$

An important point to note here is that although $\Omega_\pi(k)$ and $\omega_\pi(k)$ are momentum dependent quantities, for ease of notation we will drop the k dependence for further calculations in this section and revive it when necessary for the description of the physical processes.

It is very interesting to note that if either of $v_\pm, v_3$ is zero, then we obtain the usual expected dynamics for the pions with back to back correlations. But if we allow for either $v_\pm$ or v_3 to be non-zero as may be envisaged in the highly non-equilibrium dynamics involving the formation of a metastable DCC, then, we have terms which involve mixed interactions of the pions and sigma.

Clearly, there are two interesting cases to be considered here: $v_\pm = 0$ and $v_3 = 0$ (equivalently, $\theta = 0$) and the second case occurs with the formation of a metastable, misaligned vacuum when $\rho = \frac{\pi}{2}$.

CASE 1

For this case we use $v_\pm = 0$ and $v_3 = 0$ (or, equivalently, $\theta = 0$) showing that H reduces to

$$\begin{aligned}H &= \int \frac{d^3k}{(2\pi)^3} \left\{ \frac{\omega_\pi}{2a^3} (a_k^\dagger a_k + a_k a_k^\dagger) \right. \\ &+ \frac{\omega_\pi}{4a^3} \left(\frac{\Omega_\pi^2}{\omega_\pi^2} - 1 \right) (a_k^\dagger a_k + a_k a_k^\dagger + a_{-k} a_k + a_{-k}^\dagger a_k^\dagger) + \frac{\omega_\Sigma}{2a^3} (d_k^\dagger d_k + d_k d_k^\dagger) \\ &+ \frac{\omega_\Sigma}{4a^3} \left(\frac{\Omega_\Sigma^2}{\omega_\Sigma^2} - 1 \right) (d_k^\dagger d_k + d_k d_k^\dagger + d_{-k} d_k + d_{-k}^\dagger d_k^\dagger) \Big\} \\ &+ \left\{ \frac{\omega_\pi}{a^3} (b_k^\dagger b_k + c_k c_k^\dagger) + \frac{\omega_\pi}{2a^3} \left(\frac{\Omega_\pi^2}{\omega_\pi^2} - 1 \right) (b_k^\dagger b_k + c_k c_k^\dagger + b_{-k} c_k + c_{-k}^\dagger b_k^\dagger) \right\}\end{aligned}\quad (41)$$

This Hamiltonian has an $su(1,1)$ symmetry and can be diagonalized by a series of Bogolubov (squeezing) transformations simply given as follows: In the neutral sector, writing

$$\begin{aligned}A_k(t, r) &= \mu(r, t) a_k + \nu(r, t) a_{-k}^\dagger = U^{-1}(r, t) a_k U(r, t) \\ A_k^\dagger(t, r) &= \nu(r, t) a_{-k} + \mu(r, t) a_k^\dagger = U^{-1}(r, t) a_k^\dagger U(r, t)\end{aligned}\quad (42)$$

A similar expansion for diagonalization is done for the sigma field, with operators $D_k(t, r')$ and $D_k^\dagger(t, r')$ similar to the definition of $A_k(t, r)$ and $A_k^\dagger(t, r)$ with the d's replacing the a's. For the charged sector

$$\begin{aligned} C_k(t, r) &= \mu c_k + \nu b_{-k}^\dagger = U^{-1}(r, t) c_k U(r, t) \\ C_k^\dagger(t, r) &= \mu c_k^\dagger + \nu b_{-k} = U^{-1}(r, t) c_k^\dagger U(r, t) \end{aligned} \quad (43)$$

$$\begin{aligned} B_k(t, r) &= \mu c_{-k} + \nu b_k^\dagger = U^{-1}(r, t) b_k U(r, t) \\ B_k^\dagger(t, r) &= \mu c_{-k}^\dagger + \nu b_k = U^{-1}(r, t) b_k^\dagger U(r, t) \end{aligned} \quad (44)$$

where

$$\mu = \text{Cosh}(r) = \sqrt{\frac{1}{2} \left[\left(\frac{\Omega_\pi}{\omega_\pi} + \frac{\omega_\pi}{\Omega_\pi} \right) + 1 \right]} \quad \nu = \text{Sinh}(r) = \sqrt{\frac{1}{2} \left[\left(\frac{\Omega_\pi}{\omega_\pi} + \frac{\omega_\pi}{\Omega_\pi} \right) - 1 \right]} \quad (45)$$

and r is the squeezing parameter, is easily seen to give the usual result that $\mu^2 - \nu^2 = 1$ for a squeezing transformation. The complete unitary matrix accomplishing the squeezing transformation may be written down as

$$U(r, t) = e^{\int \frac{d^3 k}{(2\pi)^3} r(k, t) \{ (a_k^\dagger a_{-k}^\dagger - a_k a_{-k}) + (d_k^\dagger d_{-k}^\dagger - d_k d_{-k}) + (c_k b_{-k} + b_k c_{-k}) - (c_k^\dagger b_{-k}^\dagger + b_k^\dagger c_{-k}^\dagger) \}} \quad (46)$$

It should be noted here that putting together all our results for the neutral and charged sectors, the total diagonalized Hamiltonian is written in terms of various creation and annihilation operators as:

$$H = \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2a^3} \{ \Omega_\pi \{ (A_k^\dagger A_k + \frac{1}{2}) + (C_k^\dagger C_k + B_k^\dagger B_k + 1) \} + \Omega_\Sigma (D_k^\dagger D_k + \frac{1}{2}) \}. \quad (47)$$

Since the Σ field decouples, we drop all terms associated with it whenever it is not essential to our arguments allowing us to write the total dynamical Hamiltonian for the pion fields in terms of the observed pion creation and annihilation operators ($a, a^\dagger, c, c^\dagger, b$ and $b^\dagger$):

$$\begin{aligned} H_0 &= \int \frac{d^3 k}{(2\pi)^3} \frac{\Omega_\pi}{a^3} \{ 2(\mu^2 + \nu^2) (c_k^\dagger c_k + b_k^\dagger b_k + 1) + \mu\nu \{ (c_k b_{-k} + b_k c_{-k}) + (c_k^\dagger b_{-k}^\dagger + b_k^\dagger c_{-k}^\dagger) \} \\ &+ \frac{\Omega_\pi}{a^3} \{ (\mu^2 + \nu^2) (a_k^\dagger a_k + 1) + \nu\mu (a_{-k}^\dagger a_k^\dagger + a_k a_{-k}) \} \end{aligned} \quad (48)$$

This completes the analysis for the case when $\theta = 0$.

CASE 2

The second case of interest is when $\rho = \frac{\pi}{2}$. The Hamiltonian for this case, reduces to the following:

$$H_{neutral} = \int \frac{d^3k}{(2\pi)^3} \frac{1}{2} \left\{ \frac{\omega_\pi}{a^3} (a_k^\dagger a_k + a_k a_k^\dagger) + \frac{a^3 v^2 \lambda}{2\omega_\pi} (1 + 2\sin^2(\theta)) (a_k^\dagger a_k + a_k a_k^\dagger + a_{-k} a_k + a_{-k}^\dagger a_k^\dagger) \right. \\ \left. + \frac{\omega_\Sigma}{a^3} (d_k^\dagger d_k + d_k d_k^\dagger) + \frac{a^3 v^2 \lambda}{2\omega_\Sigma} (1 + 2\cos^2(\theta)) (d_k^\dagger d_k + d_k d_k^\dagger + d_{-k} d_k + d_{-k}^\dagger d_k^\dagger) \right\} \quad (49)$$

$$H_{charged} = \int \frac{d^3k}{(2\pi)^3} \left\{ \frac{\omega_\pi}{a^3} (b_k^\dagger b_k + c_k c_k^\dagger) + \frac{\omega_\pi}{2a^3} \left(\frac{\Omega_{\pi\pm}^2}{\omega_\pi^2} - 1 \right) (b_k^\dagger b_k + c_k c_k^\dagger + b_{-k} c_k + c_{-k}^\dagger b_k^\dagger) \right\} \quad (50)$$

$$H_{mixed} = \int \frac{d^3k}{(2\pi)^3} \left\{ \frac{\lambda a^3 v^2}{2} \left(\frac{2\sin(\theta)\cos(\theta)}{\sqrt{\omega_\pi \omega_\Sigma}} \right) (d_k a_{-k} + d_k a_k^\dagger + d_k^\dagger a_k + d_k^\dagger a_{-k}^\dagger) \right\} \quad (51)$$

where (for $\rho = \frac{\pi}{2}$),

$$\frac{\Omega_\pi^2}{a^6} = \frac{k^2}{a^2} + m_\pi^2 + \lambda v^2 \\ \frac{\Omega_{\pi\pm}^2}{a^6} = \frac{k^2}{a^2} + m_{\pi\pm}^2 + \lambda v^2 (1 + \sin^2(\theta)) \quad (52)$$

Unlike the case considered above, we now have a non-zero mixing term coming from the π_0 - Σ sector. Since both of these are neutral sectors, we can combine the $H_{neutral}$ and H_{mixed} terms to form a single neutral sector Hamiltonian which we will again call $H_{neutral}$ while $H_{charged}$ remains unchanged.

$$H_{neutral} = \int \frac{d^3k}{(2\pi)^3} \left\{ \begin{pmatrix} \frac{a_k^\dagger}{\sqrt{\omega_\pi}} & \frac{d_k^\dagger}{\sqrt{\omega_\Sigma}} \end{pmatrix} \begin{pmatrix} \frac{a^3}{4} \left(\frac{\Omega_\pi^2 + \omega_\pi^2}{a^6} \right) & \frac{\lambda v^2 a^3}{4} \sin(2\theta) \\ \frac{\lambda v^2 a^3}{4} \sin(2\theta) & \frac{a^3}{4} \left(\frac{\Omega_\Sigma^2 + \omega_\Sigma^2}{a^6} \right) \end{pmatrix} \begin{pmatrix} \frac{a_k}{\sqrt{\omega_\pi}} \\ \frac{d_k}{\sqrt{\omega_\Sigma}} \end{pmatrix} \right. \\ + \begin{pmatrix} \frac{a_k}{\sqrt{\omega_\pi}} & \frac{d_k}{\sqrt{\omega_\Sigma}} \end{pmatrix} \begin{pmatrix} \frac{a^3}{4} \left(\frac{\Omega_\pi^2 + \omega_\pi^2}{a^6} \right) & \frac{\lambda v^2 a^3}{4} \sin(2\theta) \\ \frac{\lambda v^2 a^3}{4} \sin(2\theta) & \frac{a^3}{4} \left(\frac{\Omega_\Sigma^2 + \omega_\Sigma^2}{a^6} \right) \end{pmatrix} \begin{pmatrix} \frac{a_k^\dagger}{\sqrt{\omega_\pi}} \\ \frac{d_k^\dagger}{\sqrt{\omega_\Sigma}} \end{pmatrix} \\ + \begin{pmatrix} \frac{a_{-k}}{\sqrt{\omega_\pi}} & \frac{d_{-k}}{\sqrt{\omega_\Sigma}} \end{pmatrix} \begin{pmatrix} \frac{\lambda v^2 a^3}{4} (1 + 2\sin^2(\theta)) & \frac{\lambda v^2 a^3}{4} \sin(2\theta) \\ \frac{\lambda v^2 a^3}{4} \sin(2\theta) & \frac{\lambda v^2 a^3}{4} (1 + 2\cos^2(\theta)) \end{pmatrix} \begin{pmatrix} \frac{a_{-k}}{\sqrt{\omega_\pi}} \\ \frac{d_{-k}}{\sqrt{\omega_\Sigma}} \end{pmatrix} \\ \left. + \begin{pmatrix} \frac{a_{-k}^\dagger}{\sqrt{\omega_\pi}} & \frac{d_{-k}^\dagger}{\sqrt{\omega_\Sigma}} \end{pmatrix} \begin{pmatrix} \frac{\lambda v^2 a^3}{4} (1 + 2\sin^2(\theta)) & \frac{\lambda v^2 a^3}{4} \sin(2\theta) \\ \frac{\lambda v^2 a^3}{4} \sin(2\theta) & \frac{\lambda v^2 a^3}{4} (1 + 2\cos^2(\theta)) \end{pmatrix} \begin{pmatrix} \frac{a_{-k}^\dagger}{\sqrt{\omega_\pi}} \\ \frac{d_{-k}^\dagger}{\sqrt{\omega_\Sigma}} \end{pmatrix} \right\} \quad (53)$$

These terms clearly show the mixings between the forward and backward pions as well as the mixing between the π_0 and Σ fields. The misalignment of the vacuum through an angle

θ induces a mixing of the two fields. The mixed fields are

$$\begin{pmatrix} A_{\theta(k)} \\ D_{\theta(k)} \end{pmatrix} = \begin{pmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} a_k \\ d_k \end{pmatrix} \quad (54)$$

Then $H_{neutral}$ can be expressed as:

$$\begin{aligned} H_{neutral} &= \begin{pmatrix} A_{\theta(k)}^\dagger & D_{\theta(k)}^\dagger \end{pmatrix} \begin{pmatrix} m_1 & 0 \\ 0 & m_2 \end{pmatrix} \begin{pmatrix} A_{\theta(k)} \\ D_{\theta(k)} \end{pmatrix} \\ &+ \begin{pmatrix} A_{\theta(k)} & D_{\theta(k)} \end{pmatrix} \begin{pmatrix} m_1 & 0 \\ 0 & m_2 \end{pmatrix} \begin{pmatrix} A_{\theta(k)}^\dagger \\ D_{\theta(k)}^\dagger \end{pmatrix} \\ &+ \begin{pmatrix} A_{\theta(-k)} & D_{\theta(-k)} \end{pmatrix} \begin{pmatrix} n_1 & 0 \\ 0 & n_2 \end{pmatrix} \begin{pmatrix} A_{\theta(k)} \\ D_{\theta(k)} \end{pmatrix} \\ &+ \begin{pmatrix} A_{\theta(-k)}^\dagger & D_{\theta(-k)}^\dagger \end{pmatrix} \begin{pmatrix} n_1 & 0 \\ 0 & n_2 \end{pmatrix} \begin{pmatrix} A_{\theta(k)}^\dagger \\ D_{\theta(k)}^\dagger \end{pmatrix}. \end{aligned} \quad (55)$$

Here,

$$\begin{aligned} 2m_2 &= \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \right) \\ &+ \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \right) \end{aligned} \quad (56)$$

$$\begin{aligned} 2m_1 &= \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \right) \\ &+ \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \right) \end{aligned} \quad (57)$$

While,

$$2n_2 = \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} - \frac{\omega_\pi}{\Omega_\pi} \right) \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} - \frac{\omega_\Sigma}{\Omega_\Sigma} \right) \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \quad (58)$$

and

$$2n_1 = \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} - \frac{\omega_\pi}{\Omega_\pi} \right) \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} - \frac{\omega_\Sigma}{\Omega_\Sigma} \right) \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \quad (59)$$

The diagonalization procedure for this case along with the dynamical consequences of this Hamiltonian will be discussed in [31].

We finally get

$$\begin{aligned} H_{neutral} = & m_1 \left(A_{\theta(k)}^\dagger A_{\theta(k)} + A_{\theta(k)} A_{\theta(k)}^\dagger \right) + n_1 \left(A_{\theta(k)} A_{\theta(-k)} + A_{\theta(k)}^\dagger A_{\theta(-k)}^\dagger \right) \\ & + m_2 \left(D_{\theta(k)}^\dagger D_{\theta(k)} + D_{\theta(k)} D_{\theta(k)}^\dagger \right) + n_2 \left(D_{\theta(k)} D_{\theta(-k)} + D_{\theta(k)}^\dagger D_{\theta(-k)}^\dagger \right) \end{aligned} \quad (60)$$

We now apply two squeezing transformations

$$\begin{aligned} F_k &= \mu A_{\theta(k)} + \nu A_{\theta(-k)}^\dagger \\ F_k^\dagger &= \mu A_{\theta(k)}^\dagger + \nu A_{\theta(-k)} \end{aligned} \quad (61)$$

and

$$\begin{aligned} G_k &= \rho D_{\theta(k)} + \sigma D_{\theta(-k)}^\dagger \\ G_k^\dagger &= \rho D_{\theta(k)}^\dagger + \sigma D_{\theta(-k)} \end{aligned} \quad (62)$$

Then,

$$[F_k, F_k^\dagger] = 1 \quad (63)$$

and

$$[G_k, G_k^\dagger] = 1 \quad (64)$$

implies that the transformations are indeed Bogolyubov transformations as

$$\mu^2 - \nu^2 = 1 \quad (65)$$

and

$$\rho^2 - \sigma^2 = 1. \quad (66)$$

The squeezing parameters μ, ν, ρ, σ are given by:

$$\begin{aligned} 2\mu^2 &= \sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \\ &+ \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \\ &+ 1. \end{aligned} \quad (67)$$

$$\begin{aligned} 2\nu^2 &= \sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \\ &+ \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \\ &- 1. \end{aligned} \quad (68)$$

$$\begin{aligned}
2\rho^2 &= \sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \\
&+ \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \\
&+ 1.
\end{aligned} \tag{69}$$

$$\begin{aligned}
2\sigma^2 &= \sqrt{\frac{\Omega_\pi}{\Omega_\Sigma}} \left(\frac{\Omega_\pi}{\omega_\pi} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) + \frac{\omega_\pi}{\Omega_\pi} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\pi}{\omega_\Sigma}} \right) \right) \\
&+ \sqrt{\frac{\Omega_\Sigma}{\Omega_\pi}} \left(\frac{\Omega_\Sigma}{\omega_\Sigma} \left(1 + \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) + \frac{\omega_\Sigma}{\Omega_\Sigma} \left(1 - \frac{1}{2} \sqrt{\frac{\omega_\Sigma}{\omega_\pi}} \right) \right) \\
&- 1.
\end{aligned} \tag{70}$$

With these definitions the neutral sector Hamiltonian is simply:

$$H_{neutral} = \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left(\left(F_k^\dagger F_k + \frac{1}{2} \right) + \left(G_k^\dagger G_k + \frac{1}{2} \right) \right) \tag{71}$$

Combining with the charged sector

$$H_{charged} = \frac{\Omega_{\pi\pm}}{a^3} \{ C_k^\dagger C_k + B_k^\dagger B_k + 1 \} \tag{72}$$

the total Hamiltonian for the case $\rho = \frac{\pi}{2}$

$$H_{\pi/2} = \int \frac{d^3 k}{(2\pi)^3} \left\{ \frac{\Omega_{\pi\pm}}{a^3} (C_k^\dagger C_k + B_k^\dagger B_k + 1) + \frac{\sqrt{\Omega_\pi \Omega_\Sigma}}{4a^3} \left((F_k^\dagger F_k + \frac{1}{2}) + (G_k^\dagger G_k + \frac{1}{2}) \right) \right\} \tag{73}$$

with

$$\begin{aligned}
\frac{\Omega_\pi^2}{a^6} &= \frac{k^2}{a^2} + m_\pi^2 + \lambda v^2 \\
\frac{\Omega_{\pi\pm}^2}{a^6} &= \frac{k^2}{a^2} + m_{\pi\pm}^2 + \lambda v^2 (1 + \sin^2(\theta))
\end{aligned} \tag{74}$$

This completes our analysis of the quantization of the Hamiltonian for the two cases mentioned above. We have taken an $O(4)$ sigma model and succeeded in quantizing the quadratic fluctuations to arrive at two Hamiltonians which provide all the required ingredients for analysing the formation, evolution and eventual decay of the DCC. Indeed, in case 2, the Hamiltonian shows explicit mixing with an angle (θ) , providing a mixing parameter and therefore a misalignment parameter in isospin space.

4 Evolution of the fluctuations and parametric amplifications

In the last section we have constructed the quantum Hamiltonians for two cases ($\theta = 0$ and $\rho = \frac{\pi}{2}$) of the $O(4)$ sigma model. We have also shown the diagonalization of the Hamiltonians so that they can be written in terms of the appropriate quantum fluctuation fields as purely quadratic Hamiltonians. In this section we shall explicitly consider the case when $\theta = \mathbf{0}$ (the dynamics of the case $\rho = \frac{\pi}{2}$ will be given in a subsequent paper [31]). We notice that H has the form of a decoupled Hamiltonian. This is easy to understand from the $S(4)$ parent. The $S(4)$ vector has been decomposed into four fields: $\pi_{\pm}, \pi_0$ and Σ being respectively the charged pions, the neutral pion and the sigma fields.

It is the sigma field which decouples in this particular Hamiltonian and therefore it can be analyzed independently of the pion fields. As our interest is in the pion fields, we can write the total dynamical Hamiltonian for the pion fields in terms of the observed pion creation and annihilation operators ($a, a^\dagger, c, c^\dagger, b$ and $b^\dagger$) in terms of the squeezing parameters as:

$$H = \int \frac{d^3k}{(2\pi)^3} \frac{\Omega_\pi}{a^3} \{2(\mu^2 + \nu^2) \{c_k^\dagger c_k + b_k^\dagger b_k + 1\} + \mu\nu \{(c_k b_{-k} + b_k c_{-k}) + (c_k^\dagger b_{-k}^\dagger + b_k^\dagger c_{-k}^\dagger)\} \\ + \frac{\Omega_\pi}{a^3} \{(\mu^2 + \nu^2) \{a_k^\dagger a_k + 1\} + (\nu\mu) \{a_{-k}^\dagger a_k^\dagger + a_k a_{-k}\}\} \quad (75)$$

We now define the bilinear operators

$$\begin{aligned} \mathcal{D} &= a_k a_{-k} + b_k c_{-k} + c_k b_{-k} = K_1^- + K_2^- + K_3^- \\ \mathcal{D}^\dagger &= a_{-k}^\dagger a_k^\dagger + c_{-k}^\dagger b_k^\dagger + b_{-k}^\dagger c_k^\dagger = K_1^+ + K_2^+ + K_3^+ \\ N &= \frac{1}{2} \{a_k^\dagger a_k + a_{-k}^\dagger a_{-k} + b_k^\dagger b_k + b_{-k}^\dagger b_{-k} + c_k^\dagger c_k + c_{-k}^\dagger c_{-k} + 3\} = K_1^0 + K_2^0 + K_3^0 \end{aligned} \quad (76)$$

and it is easy to see that they satisfy an $su(1,1)$ algebra

$$[N, \mathcal{D}] = -\mathcal{D}; \quad [N, \mathcal{D}^\dagger] = \mathcal{D}^\dagger; \quad [\mathcal{D}^\dagger, \mathcal{D}] = -2N. \quad (77)$$

The $su(1,1)$ invariant Hamiltonian for the pion fields assumes the form

$$H = \int \frac{d^3k}{(2\pi)^3} \frac{1}{a^3} 2\Omega_\pi(k, t) (\mu^2 + \nu^2) N + 2\Omega_\pi(k, t) \mu\nu (\mathcal{D} + \mathcal{D}^\dagger) \quad (78)$$

The time dependent evolution equation for the eigenstates of H is given by

$$H(t) |\psi(t)\rangle = i \frac{d}{dt} |\psi(t)\rangle \quad (79)$$

The particular $su(1,1)$ structure elucidated above provides us the solution:

$$|\psi(t)\rangle = e^{\int \frac{d^3k}{(2\pi)^3} r_k (\mathcal{D}_k^\dagger - \mathcal{D}_k)} |\psi(0)\rangle \quad (80)$$

for the evolution of the wave function immediately [36]. Here r_k is the squeezing parameter related to the physical variables $\Omega_\pi(k, t)$ and $\omega_\pi(k)$ through

$$\text{Tanh}(2r_k) = \frac{\left(\frac{\Omega_\pi(k, t)}{\omega_\pi}\right)^2 - 1}{\left(\frac{\Omega_\pi(k, t)}{\omega_\pi}\right)^2 + 1} \quad (81)$$

Where $\Omega_\pi(k, t \rightarrow \infty) = \omega_\pi(k)$. Thus in the evolution of the condensate, it is the frequency changes which bring about squeezing [34].

The diagonalized Hamiltonian H_0 can be converted into a Hamiltonian in terms of quantum fields corresponding to the operators A, B, C and their adjoints to obtain a purely quadratic Hamiltonian (the starting point of many early works on the subject of the DCC)[18, 32].

We can, for example, write

$$\frac{\Omega_\pi}{a^3}(A_k^\dagger A_k + \frac{1}{2}) = \frac{\Omega_\pi}{a^3}(A_k^\dagger A_k + A_k A_k^\dagger) = \left(\frac{\Omega_\pi}{a^3}\right)^2 \Pi_A^2(k, t) + P_{\Pi_A}^2(k, t). \quad (82)$$

Similarly for B and C, we write:

$$\begin{aligned} \frac{\Omega_\pi}{a^3}(B_k^\dagger B_k + \frac{1}{2}) &= \frac{\Omega_\pi}{a^3}(B_k^\dagger B_k + B_k B_k^\dagger) = \left(\frac{\Omega_\pi}{a^3}\right)^2 \Pi_B^2(k, t) + P_{\Pi_B}^2(k, t) \\ \frac{\Omega_\pi}{a^3}(C_k^\dagger C_k + \frac{1}{2}) &= \frac{\Omega_\pi}{a^3}(C_k^\dagger C_k + C_k C_k^\dagger) = \left(\frac{\Omega_\pi}{a^3}\right)^2 \Pi_C^2(k, t) + P_{\Pi_C}^2(k, t) \end{aligned} \quad (83)$$

$$(84)$$

The Hamiltonian H_0 can then be written as:

$$H_0(t) = \int \frac{d^3k}{(2\pi)^3} \sum_{i=A,B,C} \frac{1}{2} \left(\left(\frac{\Omega_\pi}{a^3}\right)^2 \Pi_i^2(k, t) + P_{\Pi_i}^2(k, t) \right) \quad (85)$$

The Schroedinger equation for each momentum mode is simply:

$$H_0(k, t)\psi(k, t) = i \frac{d}{dt} \psi(k, t). \quad (86)$$

If we use the Π -representation (co-ordinate space representation) for $\psi(k, t)$, then, the $su(1, 1)$ symmetry of the Hamiltonian tells us that the solution for $\psi(k, t)$ is just a Gaussian. For simplicity we work with a Gaussian of the form

$$\langle \pi_0, \pi_+, \pi_- | \psi \rangle (t) = \prod_{k,i} L_i(t) \exp(-W_i(t) \Pi_i^2) \quad (87)$$

while the complete wavefunction is:

$$\psi(t) = \int \frac{d^3k}{(2\pi)^3} \psi(k, t). \quad (88)$$

Then for each mode A,B,C,D the wave function $\psi_{k,i}(t)$ evolves as

$$i\frac{\partial\psi_{k,i}(t)}{\partial t} = (i\frac{\dot{L}_i}{L_i} - i\Pi_i^2(k)\dot{W}_i(k,t))\psi_{k,i}(t) \quad (89)$$

While

$$H_{k,i}\psi_{k,i}(t) = \frac{1}{2a^3}\{\Omega_{\pi_i}^2\Pi_i^2(k,t) - \frac{\partial^2\psi_{k,i}(t)}{\partial\Pi_i^2}\}. \quad (90)$$

Combining the above we find that $W_i(t)$ and $\psi_{k,i}(t)$ evolve as:

$$W_i(t) = -ia^3/2\frac{\dot{\psi}_{k,i}(t)}{\psi_{k,i}(t)} \quad (91)$$

$$\ddot{\psi}_{i,k}(t) + 3\frac{\dot{a}}{a}\dot{\psi}_{i,k}(t) - \frac{\Omega_{\pi_i}^2}{a^3}\psi_{i,k}(t) = 0. \quad (92)$$

The equation satisfied by the wavefunctions for each mode are then given by:

$$\begin{aligned} \ddot{\psi}_A(k,t) + \frac{3\dot{a}}{a}\dot{\psi}_A + (\frac{\Omega_\pi}{a^3})^2(k,t)\psi_A(k,t) &= 0 \\ \ddot{\psi}_B(k,t) + \frac{3\dot{a}}{a}\dot{\psi}_B + (\frac{\Omega_\pi}{a^3})^2(k,t)\psi_B(k,t) &= 0 \\ \ddot{\psi}_C(k,t) + \frac{3\dot{a}}{a}\dot{\psi}_C + (\frac{\Omega_\pi}{a^3})^2(k,t)\psi_C(k,t) &= 0 \end{aligned} \quad (93)$$

where

$$(\frac{\Omega_\pi}{a^3})^2(k,t) = (\frac{k^2}{a^2}) + m_\pi^2 + \lambda v^2 \quad (94)$$

Where it may be recalled that $A_k(t), B_k(t)$ and $C_k(t)$ are related to a_k, b_k and c_k (the physical pion operators), by the squeezing transformation given by

$$A_k(t, r) = U^{-1}(r, t)a_kU(r, t) \quad (95)$$

$$B_k(t, r) = U^{-1}(r, t)b_kU(r, t) \quad (96)$$

$$C_k(t, r) = U^{-1}(r, t)c_kU(r, t)$$

$Cosh(r) = \sqrt{\frac{1}{2}[(\frac{\Omega_\pi}{\omega_\pi} + \frac{\omega_\pi}{\Omega_\pi}) + 1]}$ $\nu = Sinh(r) = \sqrt{\frac{1}{2}[(\frac{\Omega_\pi}{\omega_\pi} + \frac{\omega_\pi}{\Omega_\pi}) - 1]}$ and r is the squeezing parameter.

$$U(r, t) = e^{\int \frac{d^3k}{(2\pi)^3} r(k, t)((a_k^\dagger a_{-k}^\dagger - a_k a_{-k}) + d_k^\dagger d_{-k}^\dagger - d_k d_{-k}) + (c_k b_{-k} + b_k c_{-k}) - (c_k^\dagger b_{-k}^\dagger + b_k^\dagger c_{-k}^\dagger)} \quad (97)$$

The expectation values of the number operator for the neutral pions for each momentum k is given by:

$$<\psi_k(t)|a_k^\dagger a_k|\psi_k(t)> = Sinh^2(r) = <\psi_k|A_k^\dagger(t)A_k(t)|\psi_k>. \quad (98)$$

A similar expression may be obtained for the charged pions.

Since we are considering the expansion of the plasma in a spherically symmetric manner as emphasized by the Robertson-Walker type metric $ds^2 = dt^2 - a(t)^2 d\underline{x}^2$, it is possible to scale the time so as to provide a conformally flat metric: we let

$$d\eta = a(t)^{-1} dt \quad (99)$$

so that

$$ds^2 = a(\eta)^2 (d\eta^2 - d\underline{x}^2). \quad (100)$$

The equations of motion given above can be transformed into ones that resemble a harmonic oscillator with time dependent frequencies. We shall write only the generic form of the above equations: In terms of the scaled time, η , we have:

$$\psi'' + \frac{2a'}{a}\psi' + (\vec{k}^2 + (m_\pi^2 + \lambda(<\Phi^2> - f_\pi^2))a^2)\psi = 0 \quad (101)$$

where a prime denotes differential wrt η . Here we have a few remarks. Firstly we note that to make contact with the dynamical equations for the pions used as starting points for analysing the DCC, we return to the point about the potential that we have chosen vs the traditional potential chosen in such studies. The traditional potential is $(\Phi_i^2 - f_\pi^2)^2$ while we have taken a potential $(\Phi_i^2)^2$. Therefore, the relationship between our work and the early studies is accomplished through a replacement $v^2 \longrightarrow (<\Phi^2>(\eta) - f_\pi^2)$. This explains the equation written above and the further analysis of this paper. Lastly, let us scale ψ :

$$\xi = a\psi \quad (102)$$

so that the equation becomes:

$$-\xi'' + V(\eta)\xi = (k^2 + m_\pi^2)\xi \quad (103)$$

where

$$V(\eta) = a^{-1} \frac{d^2 a}{d\eta^2} + m_\pi^2(1 - a^2) - \lambda(<\Phi^2> - f_\pi^2). \quad (104)$$

Thus in the symmetry broken stage $<\Phi^2> = f_\pi^2$

$$V_b(\eta) = a^{-1} \frac{d^2 a}{d\eta^2} + m_\pi^2(1 - a^2) \quad (105)$$

And in the symmetry restored stage $<\Phi^2> = 0$

$$V_r(\eta) = a^{-1} \frac{d^2 a}{d\eta^2} + m_\pi^2(1 - a^2) + \lambda a^2 f_\pi^2. \quad (106)$$

These equations have a dual personality: on the one hand they are Schroedinger like equations with η corresponding to the "spatial" like variable and $E = \omega_\pi^2$. Therefore, they allow calculation of the reflection and transmission coefficients over the "potential barrier" provided by the $V(\eta)$ term. On the other hand, they can also be looked upon as equations for time dependent harmonic oscillators with time dependent frequencies given by Ω_π^2 and ω_π^2 . These two pictures enable us to calculate the squeezing parameter dependent number operator $N(k) = \text{Sinh}^2(r(k))$ involved in the evolution of the plasma as can be seen in appendix 1.

We also note that the expansion coefficient $a(\eta)$ provides us with a control parameter on the expansion rate of the plasma while the system provides us with another parameter, which we call τ for the "rolling down" of the fields in the potential. According to the pioneering papers [14, 13], when the rate of expansion is greater then the relaxation rate of the field the DCC forms.

We now consider two cases: the first being a toy model [33] without the effects of expansion and the second being a more realistic "Baked Alaska Situation".

In the first case, let us suppose that $a(\eta) = 1$ so that

$$V(\eta) = -\lambda(< \Phi^2 > - f_\pi^2). \quad (107)$$

Then the equation for ξ is:

$$\xi'' + (k^2 + m_\pi^2 + \lambda(< \Phi^2 > - f_\pi^2))\xi = 0. \quad (108)$$

If τ is the time the state spends in the symmetry restored phase, a quench can be modelled by assuming that for $-\frac{\tau}{2} \leq \eta \leq \frac{\tau}{2}$ the vacuum expectation value $< \Phi^2 > = 0$ and for $\eta > \frac{\tau}{2}$ the vacuum relaxes to its value $< \Phi^2 > = < v^2 > \approx f_\pi^2$ (since the potential is translationally invariant, this could easily be mapped to the interval $\{0, \tau\}$, but our choice makes the potential symmetric) . For this sudden quench the problem reduces to that of transmission through a symmetric rectangular potential barrier of height $(\lambda f_\pi^2) = \frac{m_\Sigma^2}{2}$ and width τ .

The transmission coefficient for such a barrier is easily calculable [42, 41] and in terms of physically known values is:

$$T = \frac{1}{1 + \left(\frac{(\frac{m_\Sigma^2}{2})^2}{(\omega_k^2)(\frac{m_\Sigma^2}{2} - \omega_k^2)} \right) \text{Sinh}^2\left[\left(\frac{m_\Sigma^2}{2} - \omega_k^2\right)^{\frac{1}{2}} \tau\right]}. \quad (109)$$

From appendix 1 we get

$$N(k) = \frac{1 - T}{T} = \frac{\left(\frac{m_\Sigma^2}{2}\right)^2}{\omega_k^2\left(\frac{m_\Sigma^2}{2} - \omega_k^2\right)} \text{Sinh}^2\left[\left(\frac{m_\Sigma^2}{2} - \omega_k^2\right)^{\frac{1}{2}} \tau\right] \quad (110)$$

The dependence of $N(k)$ on k for different values of τ is shown in fig. 1, clearly exhibiting the amplification of the low momentum modes.

Figure 1: Shows the variation of $N(k)$ and k (in units of m_π) with $\tau = .8, .9, 1.0$ in units of m_π^{-1} for the quenched limit

Figure 1 also shows us that the longer the system stays in the state of broken symmetry the larger the DCC domains. The dependence of $N(k)$ on τ for different values of k is shown in fig. 2. Recall that by definition, the amplification of the zero modes constitutes DCC formation. Since we have a "Schrodinger" wave equation that is exactly solvable, we can also calculate the size of the DCC domains. We shall leave that for a subsequent paper [31].

This case is similar to that considered by ref [33].

For a more realistic scenario, the expansion must be included to show that the enhancement of the low energy modes and the squeezing parameter are dependent on the rate of the expansion mechanism by which the symmetry is restored. To produce substantial squeezing, we require a quenched scenario. To show this we have to compare the situation of a sudden quench with a slow adiabatic relaxation of the system from the symmetry restored stage to the symmetry broken stage. The transition between quenching and adiabaticity can be modeled in two ways in view of the dual nature of eqn(104).

We consider the expansion coefficient $a(\eta)$ to be of the form

$$a^2(\eta) = \Theta(-\eta) \text{Tanh}\left[-\frac{b}{2}\left(\eta + \frac{\tau}{2}\right)\right] + \Theta(\eta) \text{Tanh}\left[\frac{b}{2}\left(\eta - \frac{\tau}{2}\right)\right]. \quad (111)$$

Here $\frac{1}{b}$ measures the rate of the expansion and we choose b to be in units of m_π . When $b\tau \gg 1$ we have the quenched limit (fast expansion) and enhancement of low momentum modes should occur (DCC formation). When $b\tau \ll 1$ we have the adiabatic limit and no enhancement of low momentum modes should occur (no DCC formation).

Figure 2: Shows the variation of $N(k)$ with τ (units of m_π^{-1}) for $k = 0, 1$ and 2 (units of m_π) for the quenched limit

When viewed as a time dependent oscillator equation in an expanding metric we may write the equation for ξ in the symmetry restored phase as an oscillator equation

$$\xi'' + \omega_\pi^2 \xi - V_r(\eta) \xi = 0 \quad (112)$$

and in the symmetry broken stage as

$$\xi'' + \omega_\pi^2 \xi - V_b(\eta) \xi = 0. \quad (113)$$

Where $V_b(\eta)$ and $V_r(\eta)$ are given by (106,105) with the particular choice of the expansion parameter $a(\eta)$ given by (111). Thus the change in frequency from the restored to the broken stage is given by

$$V_r(\eta) - V_b(\eta) = +\frac{m_\Sigma^2}{2} a(\eta)^2 \quad (114)$$

Given that we have to calculate the transmission coefficients we need to look at the wave functions ξ in the limit $\eta \rightarrow \pm\infty$. This is possible by solving the oscillator equation with a variable frequency:

$$\xi'' + \omega_\pi^2 + \frac{m_\Sigma^2}{2} [1 - a^2(\eta)] \xi = 0. \quad (115)$$

We see that the above equation (115) satisfies the required limits $\Omega(\eta)^2 = \omega_\pi^2$ as $\eta \rightarrow \pm\infty$ and between these limits it gradually goes to a maximum at $\Omega(\eta) = \Omega_\pi^2$. The equation (115) can be converted into a Schrodinger wave equation for a Wood-Saxon potential barrier given by

$$V(\eta) = V_0 \left(\Theta(-\eta) \left(\frac{1}{1 + e^{-b(\eta + \frac{\tau}{2})}} \right) + \Theta(\eta) \left(\frac{1}{1 + e^{b(\eta - \frac{\tau}{2})}} \right) \right) \quad (116)$$

Where $V_0 = \frac{m\omega_\pi^2}{2}$. The comparison of the rectangular potential barrier with this barrier is shown in fig.3, which reveals it to be a good approximation in the adiabatic limit.

Figure 3: Shows the variation of the Wood Saxon Potential Barrier of width $\tau = 4$ with b . Large $b\tau$ gives the Rectangular Potential Barrier (quenched limit)

We take the values of the variables $E = (k^2 + \omega_\pi^2)^{\frac{1}{2}}$ and $k'^2 = E - V_0$. The transmission coefficient for this barrier is given by:

$$T_{ws} = \frac{\text{Sinh}^2(\pi \frac{2k}{b}) \text{Sinh}^2(\pi \frac{2k'}{b})}{\text{Sinh}^4(\pi \frac{(k-k')}{b}) \{4|C| \text{Sin}^2(k'b) + (|C|^2 - 1)\}} ; E \geq V_0 \quad (117)$$

and the same with $k' \rightarrow ik'$ for $E < V_0$ where $C = \frac{\text{Sinh}^2(\pi \frac{2(k+k')}{b})}{\text{Sinh}^2(\pi \frac{2(k-k')}{b})}$.

Note that for b large this reduces exactly to the rectangular potential barrier (quenched limit) transmission coefficient and for b very small this goes over to the Poschl-Teller (Eckart) Barrier transmission coefficient.

The number of particles of mode k equals .

$$N(k) = \frac{1 - (\text{Sinh}^4(\pi \frac{k-k'}{b}) \{4|C|\text{Sin}^2(k'b) + (|C|^2 - 1)\})}{\text{Sinh}^2(\pi \frac{2k}{b}) \text{Sinh}^2(\pi \frac{2k'}{b})} \quad (118)$$

Here b measures the duration of the quench. $N(k)$ vs. k is plotted in fig. 4 . We see that in the adiabatic limit of small $b\tau$, $N(k)$ is exponentially suppressed so that there is no enhancement of low momentum modes.

Figure 4: Shows the variation $N(k)$ with k for values of b in the *adiabatic limit* for Wood- Saxon barrier .

Figure 5 shows the variation of $N(k)$ with k for large values of b , showing the enhancement of low momentum modes in the quenched limit.

From the above we conclude that if expansion time ($\frac{1}{b}$) is faster than the rolling time (τ) we get the quenched limit, while, if expansion time is slower than the rolling time we get the adiabatic limit. Since in the squeezed state description $N(k) = \text{Sinh}^2 r_k$, where $r_k = r(k)$ is the squeezing parameter , we conclude that in the quenched limit the squeezing parameter is much greater than in the adiabatic limit. This demonstrates clearly the connection between the rate of expansion and squeezing and the formation of the DCC. If squeezing is large we have formed a DCC , if not then there is no DCC. This will now enable us to give signatures of DCC formation which are related to the formation process of the DCC.

5 Pion Radiation from DCC

Having shown that the dynamics of the evolution of the DCC suggests a squeezed state treatment of emerging pion waves and that this effect is more pronounced in quenched

Figure 5: Shows the variation $N(k)$ with k for values of b in the **quenched limit** for Wood- Saxon barrier .

scenario than an adiabatic one, we now proceed to show the possible experimental signals that would result. A complete treatment, with the incorporation of isospin and disorientation in isospin space for arbitrary momenta is given in [30] and [31]. For the present however, since we see an amplification of the low momentum modes we consider only the case when $k = 0$. In such case for pions near zero momentum $k \rightarrow 0$ the state (80) factors into a squeezed state for the neutral pions and a Caves- Schumaker state for the charged pions. In this limit the bilinear operators of equation (76) are

$$\begin{aligned} \mathcal{D} &= a_0^2 + b_0 c_0 + c_0 b_0 \\ \mathcal{D}^\dagger &= a_0^{\dagger 2} + c_0^\dagger b_0^\dagger + b_0^\dagger c_0^\dagger \\ N &= a_0^\dagger a_0 + b_0^\dagger b_0 + c_0^\dagger c_0 + 3/2, \end{aligned} \quad (119)$$

Thus the $k=0$ wave function is

$$|\psi\rangle = e^{r_0(\mathcal{D}^\dagger - \mathcal{D})} |\psi_0(0)\rangle = e^{r_0(a_0^{\dagger 2} + c_0^\dagger b_0^\dagger + b_0^\dagger c_0^\dagger - a_0^2 + b_0 c_0 + c_0 b_0)} |\psi_0(0)\rangle \quad (120)$$

The pion multiplicity distribution is given by

$$P_{n_0, n_+, n_-} = |\langle n_0, n_+, n_- | \psi \rangle|^2 = \langle n_0 | e^{r_0(a_0^\dagger)^2 - r_0 a_0^2} | 0 \rangle \langle n_+, n_- | e^{2r_0(b_0^\dagger c_0^\dagger - b_0 c_0)} | 0 \rangle^2 \quad (121)$$

defining $S(r_0)$ as the one mode squeezing operator

$$\begin{aligned} S(r_0) &= \langle n_0 | e^{r_0((a_0^\dagger)^2 - a_0^2)} | 0 \rangle \\ &= S_{n_0, 0}. \end{aligned} \quad (122)$$

$S^{tm}(r_0)$ is then the two mode squeezing operator

$$\begin{aligned} & \langle n_+, n_- | e^{(r_0(b_0^\dagger c_0^\dagger - b_0 c_0))} | 0 \rangle \\ & = S_{n_+, n_-, 0}^{tm}. \end{aligned} \quad (123)$$

The neutral and charged pion distribution is:

$$P_{n_0, n_c} = \langle S_{n_0, 0} \rangle^2 \langle S_{n_+, n_-, 0}^{\dagger m} \rangle^2 \quad (124)$$

which is just the product of squeezed distributions for charged and neutral pions and only even number of pions emerge. Writing $n_+ = n_- = n_c$, we get the distribution of charged particles to be

$$P_{n_c} = \sum_{n_0} P_{n_0, n_c} = \frac{(\tanh(r_0))^{2n_c}}{(\cosh(r_0))^2} \quad (125)$$

and

$$P_{n_0} = \sum_{n_c} P_{n_0, n_c} = \frac{n_0! (\tanh(r_0))^{n_0}}{((\frac{n_0}{2})!)^2 \cosh(r_0) 2^{n_0}} \quad (126)$$

The generalized squeezed eigenstate leads to products of two types of squeezed states of pions at zero momentum. The neutral pions being in a one mode squeezed state and the charged pions being in an SU(1,1) coherent or two-mode squeezed state. Thus the neutral and charged pion distributions are significantly different as the two types of states have different properties. We now illustrate the effect of squeezing in these two distributions. Figs. 6, and 7 show the difference in the charged and neutral pion distributions as we vary from the squeezing parameter from a low value to a high value.

We now illustrate the effect of quenching versus adiabaticity on these two distributions. Figs. 8 shows the difference in the charged and neutral pion distribution for as we vary from the adiabatic limit where the difference is negligible to the quenched limit where the difference is significant.

We now calculate the correlation function by first calculating the the generating function corresponding to the multiplicity distribution P_n . It is given by $Q(\lambda) = \sum_n (1 - \lambda)^n P_n$. The two particle zero momentum correlation function $G^2(0)$ is given by

$$G^2(0) = \frac{\langle n^2 \rangle - \langle n \rangle^2}{\langle n \rangle} = \frac{\frac{\partial^2 Q}{\partial \lambda^2} |_{\lambda=1}}{(\frac{\partial Q}{\partial \lambda})^2 |_{\lambda=1}} \quad (127)$$

the variation of $\frac{G_{neutral}^2}{G_{charged}^2}$ with the squeezing parameter is given in figure 10.

Figure 6: Shows the variation of P_{nc} with n for the $r_0 = 3, 3.5$ and 4

Figure 7: Shows the variation of P_{nc} with n for the $r_0 = 3, 3.5$ and 4

Figure 8: Shows the variation of P_{n0} (solid line) and P_{nc} (dashed line) with n for the *adiabatic* limit ($r_0 = 2$)

Figure 9: Shows the variation of P_{n0} (solid line) and P_{nc} (dashed line) with n for the **quenched** limit ($r_0 = 4$)

Figure 10: Shows the difference in correlations of the charged(dashed line) and neutral pions(solid line) as a function of the squeezing parameter r_0

Thus we see that in the adiabatic limit $G_{neutral}^2 \approx G_{charged}^2$, whereas in the quenched limit $G_{neutral}^2 \ll G_{charged}^2$, giving a very clear indication of the effect of DCC formation on the Bose-Einstein correlations.

To conclude this section, we have shown that the sudden quench approximation in the evolution of the disoriented chiral condensate leads to a substantial amount of squeezing which manifests itself in the dramatic difference between charged and neutral pion distributions. For an adiabatic quench the difference is much less, so that both the total multiplicity distributions of charged and neutral pions as well as their second order correlation functions are dramatic characteristic signals for the DCC and are related directly to the way in which the DCC forms. These are unambiguous, therefore they must be examined thoroughly in searches for the DCC [44].

6 Conclusion.

To conclude, in this paper we have constructed effective Hamiltonians for the evolution of the disoriented chiral condensate without and with orientation in isospin space, starting from an $O(4)$ sigma model through the inclusion of second order quantum fluctuations. We have shown that both Hamiltonians have $SU(1,1)$ symmetries leading to the presence of squeezed states in their dynamics. Unlike most earlier studies, our calculations of the effective Hamiltonians are not restricted to zero momentum and take care of back to back momentum correlations. The evolution of the wave function in an expanding metric, for one case (without orientation in isospin space) has been considered in detail. The competing

effects of the expansion rate and the rolling down time of the system from a state of restored to broken symmetry has been explicitly examined. We find that in the quenched limit (fast expansion) the low momentum modes are enhanced signaling DCC formation, whereas in the adiabatic (slow expansion) limit, no such enhancement occurs. This has been shown to be directly related to the value of the squeezing parameter. The manifestation of this difference shows up directly in the total neutral and charged multiplicity distributions at zero momentum and the second order correlation functions.

Further work is required to incorporate the effects of isospin. This is being done in a subsequent publication [30]. Furthermore, the evolution of the wave function corresponding to the Hamiltonian with orientation in isospin space is also the subject of a forthcoming communication [31]. Within this framework back to back momentum correlations and event by event analysis of the experimental signals can also be done. This will provide a solid unified picture of the various models of DCC formation, evolution and decay, together with new experimental signals. Finally, we have achieved our goal of answering Bjorken's DCC troubling questions posed at the Trento meeting [23].

- Question a: Are coherent states the right quantum DCC description, or should one go beyond to squeezed states, etc.
- Answer a: YES, one is naturally lead to squeezed states from a quantum field theoretic perspective.
- Question b: How does one link DCC thinking to quantum effects in the data, especially the BoseEinstein correlations. Is DCC just another way of talking about the same thing?
- Answer b: DCC formation leads to a significant difference between the charged and neutral pion Bose-Einstein correlations corresponding to large squeezing. So, it is not another way of talking about the same thing.
- Question c: How does one enforce quantum number conservation, especially charge?
- Answer c: Charge conservation is automatically guaranteed by the isospin analysis shown in paper [30].
- Question d: DCC production may imply anomalous bremsstrahlung, due to the large quantum fluctuations in charge. Can this be calculated from first principles?
- Answer d: This can be easily incorporated in our model and will be shown in a later communication.
- Question e: Can one really set up the problem at the quantum field theory level?
- Answer e: An emphatic YES! Albeit, the full quantum theoretical effective Hamiltonian with the contribution of the quarks still remains to be considered.

8 Appendix 1: Relationship between the transmission coefficients and squeezing parameter for a time dependent harmonic oscillator

The process of particle creation and the excitation of parametric oscillators can be related to transmission and reflection of shrodinger waves over a potential barrier. The method we

describe for the relation is closely related to ref [43] Let us consider the evolution of the wave function of the equation

$$\xi_{i,k}'' + (k^2 - V_{i,k}(\eta)) \xi_{i,k} = 0 \quad (128)$$

if we define $k^2 - V_{i,k}(\eta) = \omega(\eta)^2$, then the above equation is a time dependent harmonic oscillator $\xi''(t) + \omega^2(\eta)\xi(t) = 0$. In the event of a change in frequency of the oscillator from ω_- to ω_+ the asymptotic form of the real solution at $\eta \rightarrow \pm\infty$ is

$$\xi_{\pm}(t) = \frac{1}{2}(a_{\pm}e^{i\omega_{\pm}t} + a_{\pm}^*e^{-i\omega_{\pm}t}) \quad (129)$$

We compare this with the complex solution of a one-d oscillator treated as a reflection over a barrier $k^2 - V_{i,k}$ with η corresponding to the spatial variable of a Shrodinger type of equation :

$$\begin{aligned} \xi_{c-}(t) &= e^{i\omega_-t} + Re^{-i\omega_-t} \\ \xi_{c+}(t) &= Te^{i\omega_+t} \end{aligned} \quad (130)$$

To identify $a_- = 1 + R^*$ and $a_+ = T$

Now consider the particle creation problem modelled by a time dependent harmonic oscillator [34]. The solution can be represented by

$$\begin{aligned} \xi_{r-} &= \frac{e^{-i\omega_i t}}{\sqrt{2\omega_i}} \\ \xi_{r+}(t) &= \alpha \frac{e^{-i\omega_f t}}{\sqrt{2\omega_f t}} + \frac{\beta e^{i\omega_f t}}{\sqrt{2\omega_f t}} \end{aligned} \quad (131)$$

Now with the definition of the transmission coefficient

$$T = \frac{|\xi_{out}|^2 v_{out}}{|\xi_{in}|^2 v_i n} \quad (132)$$

If we regard t as a spatial variable then these represent reflection and transmission over a one-d barrier. In particle creation problems the potential barrier reflection and the transmission coefficient can be related to the squeezing parameter in a particle creation problem by the relation $\sinh^2 r = \frac{R}{T} = \langle n \rangle = \beta\beta^*$
